## INTRODUCTION

This publication provides data on age and sex composition for Ohio and each of its 88 counties. In addition to absolute numbers and percentages, several indices and ratios have been calculated to assist the user in interpreting the data.

Age is one of the most relevant of all population characteristics. It is the basis for understanding many of the conditions and events for an area. For example, knowing the birth rate of an area tells us little unless we know the underlying age structure. One would naturally expect a suburban community with many young couples of childbearing age to have a higher birth rate than a retirement community. Other age related issues would include school enrollment, new housing demand, entry into the labor force, new family formation and retirement related concerns. The nation's current concern for Social Security, for example, is in large part the result of increasing numbers of people in middle and older age groups combined with fewer numbers entering the labor force.

## DEFINITIONS

Following are definitions and examples of the various indices and ratios included in the tables that follow.

1. Median Age -- This is a simple average which is the mid-point of all ages in the group. For example, the state median age is 33.3 years. This means that one-half the population of Ohio is older than 33.3 years and one-half is younger than 33.3 years.
2. Percent 65 Years and Over -- This is a measure of the proportion of the population in the older age groups. In Ohio, 13.0 percent of the population is in this age group. In general, the higher the percentage of elderly in a population, the more of the total resources of that area that must be expended for their support. Payments for general welfare and medical care and provision of retirement facilities are examples of the types of expenditures that need to be provided for this segment of the population. The aged dependency ratio (defined later) is an alternative measure of this effect.
3. Percent Under 15 Years -- Areas with high percentages of young people need to expend substantial resources in support of that segment of the population. Expenses for child care, medical expenses, education and recreational facilities are examples of necessary support for the young population. In Ohio, 21.6 percent of the population is under 15 years of age.
4. Sex Ratio -- The sex ratio is an indicator of the balance (or imbalance) between the number of males and females in the population. It is computed by dividing the number of males by the number of females and multiplying by 100. Thus, the interpretation of the state sex ratio of 93.0 would be that there are 93 males for every

100 females in Ohio. A ratio of 100 would indicate an even balance between the sexes, while a ratio in excess of 100 would mean that there are more males than females in the area.

5. Sex Ratio 65 Years and Over -- This is the sex ratio of the elderly and is calculated the same way as the total sex ratio except that only the population 65 years and over is included. This ratio is usually much lower than the total sex ratio due to the longer life expectancy of females. Currently, the average life expectancy of females is five to seven years longer than for males. Thus, the Ohio aged sex ratio of 65.2 indicates that there are only 65.2 males over 65 years for every 100 females in that age group.
6. Dependency Ratios -- These are a particularly useful set of ratios which measure the proportion of dependent and productive populations in an area. In general, the productive population must provide support the young and the old in an area. For the purposes of these ratios, the young are defined as those under 20 years of age and the aged are those 65 years and over. Obviously, there are some youth of 18 and 19 years of age who are self-supporting and many in the over 65 age group are self-sufficient. Nonetheless, these ratios are useful indicators of average dependency.

Three dependency ratios are generally calculated. The youth dependency ratio (YDR) is determined by dividing the population 0-19 years by the population 20-64 years and then multiplying by 100. The aged dependency ratio (ADR) is calculated the same way except that the population 65 years and over replaces the youth population in the computation. The total dependency ratio (TDR) is simply the sum of the YDR and ADR. These ratios are interpreted as the proportion of the population that is dependent per 100 productive aged population. Thus, in Ohio the YDR of 49.9 indicates that every 100 productive aged people in the state must support approximately 50 youth. Similarly, the ADR of 22.3 means that each 100 productive aged Ohioans must provide for over 22 elderly. The TDR of 72.2 (the sum of the YDR and ADR) would be similarly interpreted. Obviously, as the ratios increase, an increase in support would be needed from the population as a whole. Those areas with the highest TDR's can generally expect to be taxed more heavily for schools, children's services, and services for the elderly than those with lower TDR's.
